# Is the Ellipsoid Formula Reliable in Prostate MRI? 

Rossy Vlăduț Teică¹, Cristina Mihaela Ciofiac¹, Lucian Mihai Florescu ${ }^{2}$, Ioana-Andreea Gheonea ${ }^{2}$<br>${ }^{1}$ Doctoral School, University of Medicine and Pharmacy of Craiova, 200349 Craiova, Romania<br>${ }^{2}$ Department of Radiology and Medical Imaging, University of Medicine and Pharmacy of Craiova, 200349 Craiova, Romania

#### Abstract

Our study seeks to study the accuracy of the ellipsoidal formula in prostate MRI of different sizes and to establish the limits of its use. The study included 31 patients with a well-visualized, intact prostatic capsule, excluding malignantly transformed prostates, as well as treated prostates, in which the contrast between the prostatic capsule and parenchyma is reduced. Each patient's prostatic volume was recalculated according to the ellipsoidal formula, and then it was compared with the prostatic volume calculated by the segmentation method. The two calculated volumes were similar, in some cases almost identical, with a slight tendency to underestimate prostate volume below $100 \mathrm{~cm}^{3}$, in total in 18 cases, on average by $7.6 \%(+/-6 \%)$, overestimation of those with a volume over $100 \mathrm{~cm}^{3}$, a total of 13 cases, on average by $3.2 \%$ ( $+/-2.5 \%$ ), and of all, in 4 cases the difference between the two formulas was below $1 \%$. There was no statistical difference between the two variables, Student's $t$-test $p$-value $=0.039$. With a precision of $92 \%$ (+/-6\%), the ellipsoidal formula can be considered accurate when it is correctly performed, but if we take into account the importance that PSA density is starting to have in diagnosis, treatment and follow-up, the calculation of a secondary value through the segmentation method or high-precision software can be motivated when the ellipsoidal formula returns a value close to a threshold.

KEYWORDS: Prostate volume, Ellipsoid formula, MRI.

## Introduction

With the increasing availability of highquality prostate magnetic resonance imaging (MRI), there is an emerging trend to base clinical decisions on it.

Prostate Imaging-Reporting and Data System (PI-RADS) [1] is the most standardized method of communication between radiologists and urologists that we currently have, classifying the risk of prostate cancer on a scale from 1-very unlikely to 3-equivocal risk and up to 5-very likely.

PI-RADS 3 lesions have proven to be controversial because of the reduced specificity for prostate cancer, and even less for clinically significant cancer [2-4].

On the other hand, since prostatic specific antigen (PSA) is produced by both healthy prostate tissue and prostate cancer, modifying the PSA value by prostate volume may enhance PSA's ability to identify patients who are prostate cancer carriers.

This concept was inspired by the well-known PSA density [5-9], which is calculated by dividing the PSA value by the volume of the prostate.

The most used method of calculating the prostate volume is, due to its shape, the ellipsoidal formula: "volume $=4 / 3 \times \pi \times \mathrm{A} \times \mathrm{B} \times \mathrm{C}$ " adapted and simplified into " $0.52 \times$ width $\times$ depth $\times$ height" [10].

Studies have shown that PSA density with a cut off of $0.1 \mathrm{ng} / \mathrm{mL} / \mathrm{mL}$ appears to be a useful marker that can stratify the risk of clinically significant prostate cancer [7,11-17].

Our study seeks to study the accuracy of the ellipsoidal formula in prostate MRI of different sizes and to establish the limits of its use.

## Methods

The study included 31 patients, chosen from our database according to the prostate size described in the examinations performed between January 2020 and August 2023 in the Medical Imaging Department of the University of Medicine and Pharmacy of Craiova using a Philips Ingenia 3.0T MRI scanner.

The age of the patients was ranging from 25 to 82 years.

Only patients with a well-visualized, intact prostatic capsule were included in the study, excluding malignantly transformed prostates, as well as treated prostates, in which the contrast between the prostatic capsule and parenchyma is reduced, as well as those with transurethral resection of the prostate.

The way in which they were selected from the database was based on the initial prostatic volume described in the report, which was between $19.96 \mathrm{~cm}^{3}$ and $256.62 \mathrm{~cm}^{3}$, slightly progressive along the entire interval, so that we obtained 6 examinations with prostate volume under $50 \mathrm{~cm}^{3}, 9$ examinations with prostate volume
between $50-100 \mathrm{~cm}^{3}$ and 16 examinations with prostate volume over $100 \mathrm{~cm}^{3}$.

Each patient's prostatic volume was recalculated according to the ellipsoidal formula (Figure 1), and then it was compared with the prostatic volume calculated by the segmentation method.

Student's t-test (2-tailed, assuming unequal variance) was used to assess the significance of the difference between the two means.

P-values under 0.05 were considered significant.

Figure 1. Left: green-segmental volume calculated at the level of the slice, blue-transverse diameter; right: yellow-cranio-caudal diameter, red-antero-posterior diameter.

Given the anatomical obliquity of the gland on the axial plane, there is a potential risk of volume overestimation if the prostate AP dimension is measured on axial imaging.

This is comparable to cutting a shape into larger slices by cutting it diagonally rather than perpendicularly.

Obtaining the anterior-posterior measurement on sagittal imaging is now advised by the most current PI-RADS update (v2.1) in order to reduce the potential risk of the so-called "salami effect" when using the ellipsoid method to calculate volume (Figure 2).

Figure 2. "Salami effect" left: the antero-posterior diameter calculated on the transverse sequence; right: the antero-posterior diameter calculated on the sagittal sequence; the transverse sequence is at the level of the yellow line in the sagittal sequence.

The segmentation method was performed by using the software integrated in the 3Dnet ${ }^{\text {TM }}$ platform provided by ${ }^{\circ}$ Biotronics3D, used by two radiologists with at least 3 years of experience in prostate mpMRI examination.

This method consists in the manual segmentation of the prostate from each transverse slice, the area of which is calculated and relative to the thickness of the slice ( 3 mm in the MRI protocol we used) the volume at the level of that
slice is obtained, and by adding all from the first slice, on which the apex of the prostate can be seen, to the last, in which its base can be seen.

This method remains accurate no matter what irregularities are present on the surface of the prostate, and that's why we consider it a good benchmark for comparison with the formula used (Figure 1).

The MRI protocol used for the sequence on which the volume of the prostate was calculated by the segmentation method consisted of an oblique axial sequence, positioned perpendicular to the prostatic urethra and parallel to the base of the urinary bladder, with a small field of view of 180 X 230 mm , but large enough to cover the entire prostate and the seminal vesicles.

In order for this method to be precise, we used small slice thicknesses of 3 mm and a spatial gap equal to these, otherwise there would have been non-visible areas that would have reduced the sensitivity of the method.

The manual segmentation of the prostate at the level of each slice was done following the prostatic capsule, a challenge representing the last apical and basal slice because the edge is not obvious due to its angulation.

In order to keep a correct report, the segmentation at these levels was done with the help of sagittal and coronal sequences.

The resulting volumes were obtained from the precise calculations obtained after the recalculation of the ellipsoidal formula, respectively the addition of the volumes of all slices of each prostate, both using values up to hundredths of a centimeter.

## Results

The results of the ellipsoidal formula can be seen in Table 1.

Table 1. T e-transverse diameter, CC e-craniocaudal diameter, AP e-antero-posterior diameter and the volume returned by the ellipsoidal formula, in ascending order.

| T $\varnothing$ | CC $\varnothing$ | AP $\varnothing$ | ELLIPSOIDAL <br> FORMULA |

Figure 3. Blue line $T$ etransverse diameter, yellow line CC e-cranio-caudal diameter, red line AP a-anteroposterior diameter and the proportion in which they change with the increase in volume of the prostate.

Figure 3 shows us how the ratio of the 3 dimensions of the prostate varies as it grows in size.

There are certainly individual variations, but it can be observed how the transverse dimension tends to change a little, the antero-posterior a little more, and the cranio-caudal changes a lot, especially in the 2nd half of the graph.

The fact that the cranio-caudal size of the prostate varies a lot was also observed in the calculation of the volume by the segmentation method, the number of slices on which the segmentation was made varying from 12 to 33 slices.

The results of the final calculations can be seen in the Table 2, where the prostatic volume calculated by the ellipsoidal formula is compared with the one calculated by the segmentation method.

Table 2. In ascending order, the volume returned by the segmentation method, by the ellipsoidal formula, and the percentage difference between them. Student test, $p=0.039$, not significant.

| SEGMENTAL <br> METHOD | ELLIPSOIDAL <br> FORMULA | PERCENTAGE <br> DIFFERENCE |
| :---: | :---: | :---: |
| $24,70 \mathrm{~cm}^{3}$ | $19,96 \mathrm{~cm}^{3}$ | $-0,191 \%$ |
| $25,52 \mathrm{~cm}^{3}$ | $24,51 \mathrm{~cm}^{3}$ | $-0,039 \%$ |
| $35,58 \mathrm{~cm}^{3}$ | $33,23 \mathrm{~cm}^{3}$ | $-0,066 \%$ |
| $36,47 \mathrm{~cm}^{3}$ | $36,14 \mathrm{~cm}^{3}$ | $-0,009 \%$ |
| $50,27 \mathrm{~cm}^{3}$ | $39,39 \mathrm{~cm}^{3}$ | $-0,216 \%$ |
| $50,54 \mathrm{~cm}^{3}$ | $44,41 \mathrm{~cm}^{3}$ | $-0,121 \%$ |
| $51,37 \mathrm{~cm}^{3}$ | $52,52 \mathrm{~cm}^{3}$ | $0,022 \%$ |
| $63,89 \mathrm{~cm}^{3}$ | $57,20 \mathrm{~cm}^{3}$ | $-0,104 \%$ |
| $64,26 \mathrm{~cm}^{3}$ | $63,22 \mathrm{~cm}^{3}$ | $-0,016 \%$ |
| $66,83 \mathrm{~cm}^{3}$ | $63,55 \mathrm{~cm}^{3}$ | $-0,049 \%$ |
| $76,86 \mathrm{~cm}^{3}$ | $72,12 \mathrm{~cm}^{3}$ | $-0,061 \%$ |
| $79,54 \mathrm{~cm}^{3}$ | $75,37 \mathrm{~cm}^{3}$ | $-0,052 \%$ |
| $94,84 \mathrm{~cm}^{3}$ | $82,07 \mathrm{~cm}^{3}$ | $-0,134 \%$ |
| $102,45 \mathrm{~cm}^{3}$ | $89,47 \mathrm{~cm}^{3}$ | $-0,126 \%$ |
| $101,67 \mathrm{~cm}^{3}$ | $95,04 \mathrm{~cm}^{3}$ | $-0,065 \%$ |
| $104,32 \mathrm{~cm}^{3}$ | $101,44 \mathrm{~cm}^{3}$ | $-0,027 \%$ |
| $109,85 \mathrm{~cm}^{3}$ | $107,09 \mathrm{~cm}^{3}$ | $-0,025 \%$ |
| $115,96 \mathrm{~cm}^{3}$ | $122,67 \mathrm{~cm}^{3}$ | $0,057 \%$ |
| $122,46 \mathrm{~cm}^{3}$ | $124,79 \mathrm{~cm}^{3}$ | $0,019 \%$ |
| $135,73 \mathrm{~cm}^{3}$ | $129,77 \mathrm{~cm}^{3}$ | $-0,043 \%$ |
| $130,54 \mathrm{~cm}^{3}$ | $135,71 \mathrm{~cm}^{3}$ | $0,039 \%$ |
| $139,36 \mathrm{~cm}^{3}$ | $136,58 \mathrm{~cm}^{3}$ | $-0,019 \%$ |
| $135,17 \mathrm{~cm}^{3}$ | $137,64 \mathrm{~cm}^{3}$ | $0,018 \%$ |
| $143,43 \mathrm{~cm}^{3}$ | $144,09 \mathrm{~cm}^{3}$ | $0,004 \%$ |
| $143,03 \mathrm{~cm}^{3}$ | $149,19 \mathrm{~cm}^{3}$ | $0,043 \%$ |
| $163,81 \mathrm{~cm}^{3}$ | $164,22 \mathrm{~cm}^{3}$ | $0,002 \%$ |
| $180,81 \mathrm{~cm}^{3}$ | $186,92 \mathrm{~cm}^{3}$ | $0,033 \%$ |
| $195,21 \mathrm{~cm}^{3}$ | $196,09 \mathrm{~cm}^{3}$ | $0,004 \%$ |
| $190,88 \mathrm{~cm}^{3}$ | $199,06 \mathrm{~cm}^{3}$ | $0,042 \%$ |
| $209,41 \mathrm{~cm}^{3}$ | $229,03 \mathrm{~cm}^{3}$ | $0,093 \%$ |
| $250,18 \mathrm{~cm}^{3}$ | $259,61 \mathrm{~cm}^{3}$ | $0,037 \%$ |
| 20 |  |  |

The two calculated volumes were similar, in some cases almost identical, with a slight tendency to underestimate prostate volume below $100 \mathrm{~cm}^{3}$, in total in 18 cases, on average by $7.6 \%$ (+/-6\%), overestimation of those with a volume over $100 \mathrm{~cm}^{3}$, a total of 13 cases, on average by $3.2 \% ~(+/-2.5 \%)$, and of all, in 4 cases the difference between the two formulas was below $1 \%$.

There was no statistical difference between the two variables, Student's t -test p -value $=0.039$.

## Discussions

The diagnosis, treatment, and follow-up of benign and malignant prostate diseases depend on an accurate calculation of prostate volume.

Studies have shown that knowing the PSA density, and implicitly the prostate volume, are useful in stratifying the risk of clinically significant prostate cancer, together with the PI-RADS score [7,11-17].

Schoots et al. [18] demonstrated that intermediate-risk PI-RADS 3 lesions with PSA density $<0.10 \mathrm{ng} / \mathrm{mL} / \mathrm{mL}$ have a $4 \%$ risk of clinically significant disease, low enough for imaging monitoring to be more motivated compared to biopsy.

In the event that this risk adaptation will be adopted by urologists, additional attention will be needed to calculate the prostate volume in the case of PI-RADS 3 lesions, but also PI-RADS 2 lesions, because the same paper showed that $18 \%$ of patients with PI-RADS 1 and 2 but with PSA density $>0.2 \mathrm{ng} / \mathrm{mL} / \mathrm{mL}$ shows significant disease.

Although it is the most widely used formula for MRI volume determination, reports of the accuracy of the ellipsoid formula are mixed, there are studies that say it overestimates [19], as well as those that say it underestimates [10].

Our paper partially contradicts these statements, even if we included in the study only prostate MRI examinations without significant pathology, but we had to do so because otherwise it would have prevented us from calculating the segmental method with precision.

The PSA density partially loses its importance in the case of malignantly transformed prostates, so we consider this prior filtering of the examinations useful, the only defect being the relatively small number of cases used in the study.

Figure 4. Blue line-the variation of the prostatic volume calculated by the segmental method; orange line-the variation of prostatic volume calculated by the ellipsoidal formula.

The tendency of the ellipsoidal formula was to underestimate the volume of normal and large prostates ( $<100 \mathrm{~cm}^{3}$ ) and to overestimate those of very large sizes ( $>100 \mathrm{~cm}^{3}$ ).

The overestimation can be attributed to the loss of the regular contour when they grow a lot in size, especially in the cranio-caudal axis (Figure 3 and 4), but the normal and large ones are underestimated exclusively due to the fact that the prostate is not a perfect ellipsoid, and the cases in which the ellipsoidal formula of estimated prostatic volume with an accuracy greater than $99 \%$, we can consider them coincidental rather than effective.

Because the segmentation method is insidious, another alternative to calculating the prostate volume is the trained, high-precision software [20,21] that can suggest a second opinion when the PSA density is close to threshold values such as $0.1 \mathrm{ng} / \mathrm{mL} / \mathrm{mL}$ in PI-RADS 3 lesions or $0.2 \mathrm{ng} / \mathrm{mL} / \mathrm{mL}$ in PI-RADS 2 lesions.

## Conclusions

With a precision of $92 \%$ (+/-6\%), the ellipsoidal formula can be considered accurate when it is correctly performed, but if we take into account the importance that PSA density is starting to have in diagnosis, treatment and follow-up, the calculation of a secondary value through the segmentation method or highprecision software can be motivated when the ellipsoidal formula returns a value close to a threshold.
